U.S. ELECTRONICS RECOVERY · PHILIPPINE MINING · EXPORT LICENSED

Critical minerals. Secured for America.

Apex SCM Corp. collects, processes and refines electronics in the United States. Across the Pacific, we mine gold and silver for our own account in the Philippines, and the same ground yields the critical minerals American industry depends on. With our export license in place, we are seeking a U.S. refinery or off-take partner to strengthen their supply chain.

01 · THE FOUNDATION

Established operations on both sides of the Pacific: electronics processing and refining in the USA, mining in the Philippines.

02 · THE ACCESS

Our own mine, producing gold and silver alongside tungsten, copper, uranium, cobalt, antimony, zinc, lead and iron.

03 · THE LICENSE

An export license in hand, so material can move from the Philippines to refineries in the United States.

01 / IN THE UNITED STATES

Electronics: collected, processed, refined.

We are an established operator in the collection, secure processing and refining of end-of-life electronics. Our lifecycle model connects data destruction and refurbishment with material recovery and reintegration, under chain-of-custody control and documented outcomes.

02 / IN THE PHILIPPINES

Mining gold and silver, with more in the ground.

We mine gold and silver for ourselves. The same workings carry a wider set of critical minerals that we are open to supplying onward. Our field record documents surface excavation and underground workings, and the technical review covers gold-focused exploration north of Masara in Mindanao.

Rock specimen · Original company-supplied photograph

WHAT OUR MINE PRODUCES

MINED FOR OUR OWN ACCOUNT	Gold · Silver
OPEN TO U.S. OFF-TAKE PARTNERS	Tungsten · Copper · Uranium · Cobalt · Antimony · Zinc · Lead · Iron

The partner we're seeking.

A U.S. refinery or off-taker that needs a dependable, licensed source of critical minerals. We bring the ground, the operations and the export license; the right partner brings the demand. Our mineral supply is directed exclusively to the United States.

Let's secure the supply chain together.

Refiners, off-takers, industry and capital partners.

THE TECHNICAL BASIS FOR EXPLORATION

Reading the ground.

The review places the proposed area north of Masara and west of Lake Leonard in Mindanao. It brings together several layers of evidence to understand the terrain, the regional mineralizing environment and the structures that may guide further exploration.

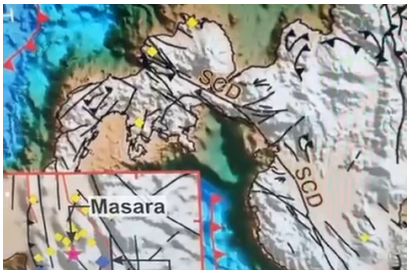

Elevation model and radar view · Technical briefing, V01

01 / Topography & radar imagery

A digital elevation model (DEM) shows the terrain in color-coded elevation bands. Three-dimensional relief views and radar/satellite imagery provide complementary views of the same proposed area. Together, the images establish the landscape context around Masara, Lake Leonard and the illustrated project outline.

Purpose: understand the physical setting before defining field profiles.

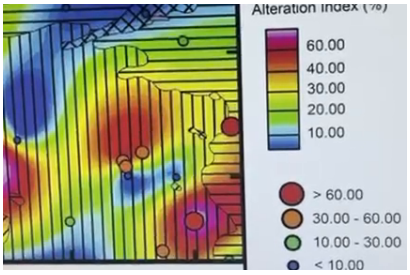

Regional geological map detail · Technical briefing, V03

02 / Rock units, faults & vein directions

The review discusses the Eocene Masara Formation and intrusive rocks including biotite diorite porphyry, quartz diorite, dacite and tonalite. It relates these to epithermal quartz-vein gold systems and porphyry copper–gold associations. The narrator highlights east–west and northwest–southeast vein trends; the slides also discuss structural control associated with the Philippine Fault Zone.

Purpose: identify geological relationships and structural trends to investigate.

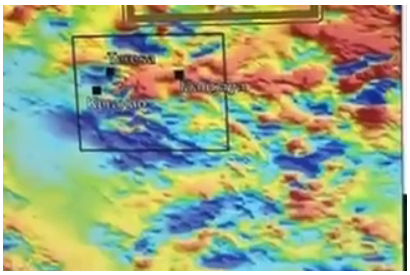

Alteration map detail · Technical briefing, V03

03 / Hydrothermal alteration patterns

The regional maps distinguish potassic, chlorite–sericite and propylitic zones. The slides describe alteration overprinting and localized advanced argillic alteration, alongside an alteration-index map. These patterns record changes to the rocks associated with the mineralizing system and provide another basis for comparing prospective areas. The index measures alteration intensity.

Purpose: combine alteration patterns with geology and structure when considering targets.

Total magnetic intensity detail · Technical briefing, V03

04 / Aeromagnetic interpretation

The slides compare total magnetic intensity (TMI), reduction-to-equator (RTE), reduction-to-pole (RTP) and a 500 m upward-continued view. The presenter uses the magnetic patterns as indicators of potentially favorable host rocks. These processed maps help examine regional patterns and structural relationships; they do not establish gold content or reserves.

Purpose: use magnetic interpretation alongside geological evidence to guide follow-up.

Maps are crops from the supplied technical briefing. They provide regional and proposed-area context; the review is distinct from a completed site-specific survey or a mineral resource estimate. The next field steps are outlined on page 3.

WHAT IS DOCUMENTED · WHAT IS PROPOSED

From fieldwork to next steps.

The field record shows excavation and rock inspection at surface and underground. The briefing then sets out how location confirmation, profile planning and samples could improve understanding of the exploration area.

Surface video · 01:05

SURFACE EXCAVATION

A tracked excavator exposes material while personnel inspect the rock and work with hand tools.

Underground video · 00:51

UNDERGROUND WORKINGS

Lit rock faces, timber supports and close inspection document activity within the workings.

Original company-supplied photograph

ROCK MATERIAL

Photographs of fragments and specimens support discussion of the material observed at the site.

Proposed-area map · Technical briefing, V05

Illustrative area: 4.5 × 2.3 km

The presenter drew this proposal from one supplied location point. A surveyor is recommended to establish the exact location and boundary coordinates before fixing the program.

The recommended field program

01 **CONFIRM THE FOOTPRINT**
Establish the site and its limits with surveyor-confirmed GPS coordinates and boundary points.

02 **DEFINE GEOPHYSICAL PROFILES**
Lay out profiles within the confirmed area, informed by the mapped geological setting and vein trends.

03 **DRILL AND COLLECT SAMPLES**
Investigate selected positions along the proposed profiles to understand whether veins continue between locations.

04 **INFORM THE NEXT MINING DECISIONS**
Use the findings to improve understanding of vein direction and continuity and guide where subsequent work should begin.

Our commercial focus: the United States. We mine gold and silver for ourselves. The critical minerals alongside them, tungsten, copper, uranium, cobalt, antimony, zinc, lead and iron, are open to the right U.S. refining or off-take partner, backed by our export license.
